**E-mail: cecilia.tarantino@ph.tum.de*

The results of an extensive flavour physics analysis in the Littlest Higgs model with T-parity are presented. In particular, mixing and CP-violation in $K^0 - \bar{K}^0$ and $B_{d,s}^0 - \bar{B}_{d,s}^0$ systems have been studied. Several scenarios defined by the values of mirror quark masses and the parameters of the new flavour mixing matrix V_{Hd} have been considered. A very interesting scenario is identified, where the well-known kaon constraints are satisfied, the $\sin 2\beta$ and ΔM_s issues are improved w.r.t. the Standard Model and visible effects could be soon found in A_{SL}^s and $S_{\psi\phi}$.

Keywords: Beyond Standard Model; CP violation.

1. The Littlest Higgs Model

The Standard Model (SM) is in excellent agreement with the results of particle physics experiments, in particular with the electroweak (ew) precision measurements, thus suggesting that the SM cutoff scale is at least as large as 10 TeV. Having such a relatively high cutoff, however, the SM requires unsatisfactory fine-tuning to yield a correct ($\approx 10^2$ GeV) scale for the Higgs mass, being the Higgs boson a fundamental scalar with one-loop quadratically divergent corrections to its squared mass. This “little hierarchy problem” has been one of the main motivations to elaborate models of physics beyond the SM. While Supersymmetry is at present the leading candidate, different proposals have been formulated more recently. Among them, Little Higgs models play an important role, being perturbatively computable up to about 10 TeV and with a rather small number of parameters.

In Little Higgs models¹ the Higgs is interpreted as a Nambu-Goldstone boson (NGB) corresponding to a spontaneously broken global symmetry, thus explaining its lightness. An exact NGB, however, would have only derivative interactions. Gauge and Yukawa interactions of the Higgs have to

be incorporated. This can be done without generating quadratically divergent one-loop contributions to the Higgs mass, through the so-called *collective symmetry breaking*. The collective symmetry breaking (SB) has the peculiarity of generating the Higgs mass only when two or more couplings in the Lagrangian are non-vanishing. This mechanism is diagrammatically realized through the cancellation of the SM quadratic divergences by the contributions of new particles with masses around 1 TeV.

The most economical, in matter content, Little Higgs model is the Littlest Higgs (LH)², where the global group $SU(5)$ is spontaneously broken into $SO(5)$ at the scale $f \approx \mathcal{O}(1 \text{ TeV})$ and the ew sector of the SM is embedded in an $SU(5)/SO(5)$ non-linear sigma model. Gauge and Yukawa Higgs interactions are introduced by gauging the subgroup of $SU(5)$: $[SU(2) \times U(1)]_1 \times [SU(2) \times U(1)]_2$, with gauge couplings respectively equal to g_1, g'_1, g_2, g'_2 . The key feature for the realization of collective SB is that the two gauge factors commute with a different $SU(3)$ global symmetry subgroup of $SU(5)$, implying that neither of the gauge factors alone can generate a potential for the Higgs. Consequently, quadratic corrections to the squared Higgs

mass involve two couplings and cannot appear at one-loop. In the LH model, the new particles appearing at the TeV scales are the heavy gauge bosons ($W_H^\pm, Z_H, A_H$) the heavy top (T) and the scalar triplet Φ .

In the LH model, significant corrections to ew observables come from tree-level heavy gauge boson contributions and the triplet vacuum expectation value (vev) which breaks the custodial $SU(2)$ symmetry. Consequently, ew precision tests are satisfied for values of the NP scale $f \geq 2 - 3 \text{ TeV}^{3,4}$, too large to solve the little hierarchy problem. Motivated by reconciling the LH model with ew precision tests, Cheng and Low⁵ proposed to enlarge the symmetry structure of the theory by introducing a discrete symmetry called T-parity. T-parity acts as an automorphism which exchanges the $[SU(2) \times SU(1)]_1$ and $[SU(2) \times SU(1)]_2$ gauge factors. The invariance of the theory under this automorphism implies $g_1 = g_2$ and $g'_1 = g'_2$. Furthermore, in studied observables, T-parity explicitly forbids the tree-level contributions of heavy gauge bosons and the interactions that induced the triplet vev. The custodial $SU(2)$ symmetry is restored and the compatibility with ew precision data is obtained already for smaller values of the NP scale, $f \geq 500 \text{ GeV}^6$. Another important consequence is that particle fields are T-even or T-odd under T-parity. T-even states are the SM particles and the heavy top T_+ . T-odd states, instead, are the heavy gauge bosons $W_H^\pm, Z_H, A_H$, the scalar triplet Φ and additional particles required by T-parity: the odd heavy top T_- and the so-called mirror fermions, i.e., fermions corresponding to the SM ones but with opposite T-parity and $\mathcal{O}(1 \text{ TeV})$ mass. Mirror fermions are characterized by new flavour interactions with SM fermions and heavy gauge bosons, which involve in the quark sector two new unitary mixing matrices analogous to the Cabibbo-Kobayashi-Maskawa (CKM) matrix V_{CKM} . They are V_{Hd} and V_{Hu} , respectively involved

when the SM quark is of down- or up-type, and satisfying $V_{Hu}^\dagger V_{Hd} = V_{CKM}^{7,8}$.^a The Littlest Higgs model with T-parity (LHT) does not belong to the Minimal Flavour Violation (MFV) class of models, where the CKM matrix is the only source of flavour and CP-violation. The LHT peculiarities are the rather small number of new particles and parameters (the SB scale f , the parameter x_L describing T_+ mass and interactions, the mirror fermion masses and V_{Hd} parameters), the absence of new operators in addition to the SM ones and, at the same time, the possibility to have visible effects in flavour observables.

2. LHT Flavour Analysis

Several studies of flavour physics in the LH model without T-parity have been performed in the last three years¹⁰. Without T-parity, mirror fermions and new sources of flavour and CP-violation are absent, the LH model is a MFV model and NP contributions result to be very small.

More recently, the first flavour physics analysis in the LHT model has been performed⁸, where the mass differences ΔM_K , $\Delta M_{d,s}$, ΔM_D and the CP-violation parameter ε_K have been studied. We have confirmed¹¹ their analytic expressions and performed a wider phenomenological analysis in the LHT model, including also the width differences $\Delta \Gamma_{d,s}$, the radiative decays $B \rightarrow X_{s,d} \gamma$ and the CP-violating asymmetries $A_{CP}(B_d \rightarrow \psi K_S)$, $A_{CP}(B_s \rightarrow \psi \phi)$ and $A_{SL}^{d,s}$. Two interesting issues considered in our analysis are the possible discrepancy between the values of $\sin 2\beta$ following directly from $A_{CP}(B_d \rightarrow \psi K_S)$ and indirectly from the usual analysis of the unitarity triangle^{12,13,14}, and the recent measurement of ΔM_s by the CDF and D0 collaborations¹⁵,

^a V_{Hd} contains 3 angles, like V_{CKM} , but 3 phases⁹, i.e. two additional phases relative to the CKM matrix.

that although close to the SM value is slightly smaller than expected. An important result of our study is that in the LHT model ΔM_s can be smaller than in the SM, as experimentally indicated, and that, for the same range of parameters, the “ $\sin 2\beta$ ” discrepancy can be cured and visible effects in observables unknown or with still large uncertainties like $A_{CP}(B_s \rightarrow \psi\phi)$ and $A_{SL}^{d,s}$ can be found.

In our LHT flavour analysis we have considered several scenarios for the structure of the V_{Hd} matrix and the mass spectrum of mirror fermions in order to gain a global view over possible signatures of mirror fermions and T-even contributions. In all these scenarios the two additional phases of V_{Hd} , whose impact is numerically small, have been set to zero. The CKM parameters entering the analysis have been taken from tree level decays only, where NP effects can be neglected. In order to simplify the numerical analysis we have set all non-perturbative parameters to their central values, while allowing ΔM_K , ε_K , ΔM_d , ΔM_s , $\Delta M_s/\Delta M_d$ and $S_{\psi K_S}$ to differ from their experimental values by $\pm 50\%$, $\pm 40\%$, $\pm 40\%$, $\pm 40\%$, $\pm 20\%$ and $\pm 8\%$, respectively. This rather conservative choice guarantees that interesting effects are not missed. In scenarios 3 – 5, described below, the parameters f and x_L have been fixed to $f = 1$ TeV and $x_L = 0.5$ in accordance with ew precision tests. The main features of the five studied scenarios are described below.

Scenario 1: Mirror fermions are degenerate in mass, therefore only the T-even sector contributes. This is the MFV limit of the LHT model where a new phase curing the $\sin 2\beta$ discrepancy cannot appear and $(\Delta M_s)_{LHT} \geq (\Delta M_s)_{SM}$, disfavored by the CDF measurement¹⁵, is found.

Scenario 2: A scan over non-degenerate mirror fermion masses is performed, while V_{Hd} has the same structure of the CKM matrix ($V_{Hd} = V_{CKM}$). Similarly to the previous scenario, no improvements concerning

the $\sin 2\beta$ and ΔM_s issues are achieved.

Scenario 3: Mirror fermion masses are $m_{H1} = 400$ GeV, $m_{H2} = 500$ GeV, $m_{H3} = 600$ GeV, while for V_{Hd} an arbitrary structure is allowed. The freedom in V_{Hd} allows to soften the $\sin 2\beta$ discrepancy, while for ΔM_s no improvement is found.

Scenario 4: This is the most interesting scenario where the ΔM_s and $\sin 2\beta$ issues can be improved and, simultaneously, visible departures from the SM and MFV can be obtained, mainly in A_{SL}^s and $A_{CP}(B_s \rightarrow \psi\phi)$. Here $m_{H1} \approx m_{H2} \approx 500$ GeV, $m_{H3} = 1000$ GeV, $1/\sqrt{2} \leq s_{12}^d \leq 0.99$, $5 \cdot 10^{-5} \leq s_{23}^d \leq 2 \cdot 10^{-4}$, $4 \cdot 10^{-2} \leq s_{13}^d \leq 0.6$ and the phase δ_{13}^d is arbitrary. The latter sines and phase are those describing V_{Hd} in a parameterization similar to the usual V_{CKM} ’s one. The very different hierarchy of V_{Hd} w.r.t. V_{CKM} , with a large complex phase in the $(V_{Hd})_{32}$ element assures large CP-violating effects in the $B_s^0 - \bar{B}_s^0$ system. Moreover, ΔM_s can be smaller than its SM value and interesting effects in the $B_d^0 - \bar{B}_d^0$ system are found. The effects in the kaon system are unimportant, being the first two mirror fermion masses almost degenerate, as required by the ΔM_K and ε_K constraints.

Scenario 5: In all the previous scenarios the SM solution ($71^\circ \pm 16^\circ$) has been considered for the angle γ such that only small departures from the SM in the $B_d^0 - \bar{B}_d^0$ system can be consistent with the data. In this last scenario, instead, we have assumed the second solution $\gamma = -109^\circ \pm 16^\circ$. Moreover, $m_{H1} = 500$ GeV, $m_{H2} = 450$ GeV, $m_{H3} = 1000$ GeV, $5 \cdot 10^{-5} \leq s_{12}^d \leq 0.015$, $2 \cdot 10^{-2} \leq s_{23}^d \leq 4 \cdot 10^{-2}$, $0.2 \leq s_{13}^d \leq 0.5$ and the phase δ_{13}^d is arbitrary. We have found that with this V_{Hd} hierarchy, inverted relative to the CKM one and also different from that in scenario 4, a rough consistency with the existing data can be obtained. In spite of that, the combined measurements of A_{SL}^d and $\cos 2\beta$ and the indirect experimental estimate of A_{SL}^s make this scenario very unlikely.

In conclusion, we stress that in the interesting scenario 4, significant enhancements of the CP-asymmetries $A_{CP}(B_s \rightarrow \psi\phi)$ ($\approx 5 - 10$ times larger than in the SM) and A_{SL}^s ($\approx 10 - 20$ times larger than in the SM) are possible as shown in Fig.1, while satisfying all existing constraints, in particular from the $B \rightarrow X_s \gamma$ decay, as shown in Fig.2. In order to improve the LHT flavour analysis the next step is certainly the inclusion of rare decays in both K and $B_{d,s}$ meson systems. This study has been just performed¹⁶ finding that visible effects in observables accessible to future experiments, mainly in K physics, are possible.

Acknowledgments

I would like to thank the organizers of the interesting and pleasant conference ICHEP'06,

Fig. 1. A_{SL}^s as a function of $S_{\psi\phi}$ ($A_{CP}(B_s \rightarrow \psi\phi) = S_{\psi\phi} \sin(\Delta M_s t)$), in Scenario 4.

Fig. 2. Correlation between ΔM_s and $Br(B \rightarrow X_s \gamma)$, in Scenario 4.
